Course Code: CSA0801

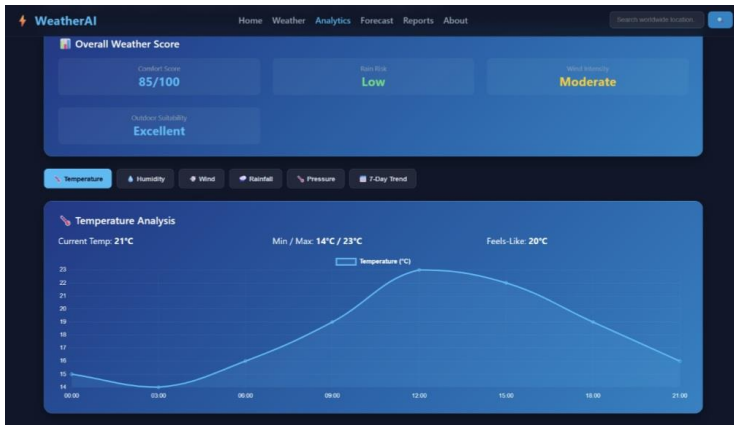

Slot: C

Course Name: Python Programming

Course Faculty: Dr. Sankar S

Project Title: Analytical Platform for Weather Forecasting

Module Photographs: (3 photographs –Module Photo, Individual student contribution module work in the project and presentation image)

Project Description: (here you write what you did in this project (contribution) including Model Description)

The **Analytical Platform for Weather Forecasting** is a web-based system developed to provide accurate, understandable, and useful information about weather conditions. The platform collects and analyzes important weather parameters such as temperature, humidity, wind speed, atmospheric pressure, and rainfall. It uses historical and real-time weather data along with analytical and forecasting techniques to identify patterns and predict future weather conditions. Interactive graphs, charts, weather icons, and visual indicators help users understand weather trends easily. The system provides location-based weather information and a **7-day weather forecast**, allowing users to plan their daily activities effectively. Users can also select individual parameters such as humidity and wind speed to view detailed analytical information. The platform can generate well-organized weather reports that can be downloaded in PDF format for future reference. By combining data collection, analytics, visualization, and forecasting, the system provides a simple and efficient solution for understanding changing weather conditions and supporting better planning and decision-making.
